Abstract In order to calculate the wide-band frequency characteristics of the H-plane circular bend of rectangular waveguide with an arbitrary bend curvature including sharp bend and any bend angle, a systematic method based on planar circuit theory is proposed; equivalent multi-transmission line model are formulated and successfully applied to the practical structure, as well as E-plane circular bend case. [7]

1. Introduction

H-plane circular bend of the rectangular waveguide shown in Fig. 1, is an important waveguide component. However, so far obtained analytical method and its numerical results [1-5] are limited to the gradual bend case only. Therefore, analytical method and numerical data which can cover wide bend parameters (= bend curvature C and bend angle \( \alpha \) which are explained in Fig. 1) including sharp bend are strongly needed not only for academic interest but also for the integration of microwave circuit.

This paper treats the above problem based on the equivalent multi-transmission line network representation [6], which is derived from H-plane planar circuit equations [8]. Practically, how to calculate the network parameters is explained in general, based on planar circuit theory and then actual network parameters are calculated as a function of normalized frequency with bend curvature parameter C. Finally, based on these parameters, the frequency characteristics for right angle H-plane circular bend case is calculated for wide range of bend curvature as an example.

2. Equivalent multi-transmission line network representation

H-plane curved rectangular waveguide \((d \times W)\) can be considered to be a H-plane planar circuit as a whole, where field components and planar voltage/current are related by \((B),(C),(D)\) in Table 1 [8].

Hence, the frequency characteristics of the curved rectangular waveguide shown in Fig. 1 can be given by solving planar circuit equations \((E),(G)\) in Table 1 directly under the short circuited boundary condition \((F)\) and TE10 dominant mode excitation condition. Here, instead, the frequency characteristics are calculated based on the equivalent multi-transmission line network representation given in Fig. 2. This equivalent network representation is derived by the modal analysis of the planar circuit, applying the separation

\[ C = \frac{b}{a} : \text{bend curvature parameter} \]

(R: average radius of the curved waveguide)

Planar Circuit Equations with B. C.

\[
\begin{align*}
\text{grad} V^e &= -j \alpha \beta^e J^e \\
\text{div} J^e &= -j \beta^e V^e \\
V^e &= 0 \quad \text{(or} \quad J^e \times n = 0) \\
\end{align*}
\]

Planar Immittance

\[
\begin{align*}
\chi^e &= \alpha \mu_0 d, \quad \beta^e = \frac{\alpha \varepsilon_0}{d} \\
\end{align*}
\]

Table 1 H-plane planar circuit equations and the relation between field components and planar voltage/current with boundary condition.
of variable technique to the planar circuit structure (Table 2 [6]).

In the straight rectangular waveguide section (A1 in Table 2), where 1-s-z coordinate system is defined, p-th mode voltage and current are given by (B1), where p-th width mode \( f_p^w(s) \) is also defined; modal voltage and modal current along \( \ell \), \( V_p(\ell) \) and \( I_p(\ell) \), are related by the transmission line equations (Ci) with p-th mode characteristic impedance \( Z_{cp}^w \) and propagation constant \( \beta_p^w \).

In the curved rectangular waveguide section (A2 in Table 2), where \( r-\theta-z \) coordinate system is defined, p-th mode voltage and current are given by (Bz), where n-th radial mode function \( R_n^r(r) \) is defined by (A) in Table 3; the modal voltage and modal current along \( \theta \), \( V_p^n(\theta) \) and \( I_p^n(\theta) \), are related by the transmission line equations (C2) with n-th mode characteristic impedance \( Z_{cn}^r \) and circular (azimuthal) propagation constant \( v_c^r \). The coupling between p-th mode in straight waveguide and n-th mode in the circular bend is defined by ideal transformer ratio and given by eq.(1)

\[
n_{n,p} \equiv \frac{1}{W} \int_{s_0}^{s} f_p^w(s) f_p^w(s) \, ds (i = \#1, \#2) \tag{1}
\]

Hence, the whole equivalent network becomes that in Fig.2. Also 2-port (input/output) mode impedance matrix is given by eq.(2)

\[
Z_{p,q} = \sum_{n=0}^{\infty} \left( n_{n,p} \right)^2 \left[ \begin{array}{cc} Z_{cp}^w \coth v_c^w \alpha & Z_{cn}^r \csc v_c^r \alpha \\ Z_{cn}^w \csc v_c^w \alpha & Z_{cp}^r \coth v_c^r \alpha \end{array} \right] \left( n_{n,q} \right)^2 \tag{2}
\]

#### Separation of variable with p-th mode width function \( f_p^w(s) \)

- \( V_p^n(\ell, s) = V_p^n(s) f_p^w(s) \)
- \( J_p^n(\ell, s) = [J_p^n(s)] f_p^w(s) \)
- \( J_p^n(\ell, s) = -\frac{1}{X_p^w} \sin(p \pi s / W) (p = 1, 2, \ldots) \)

#### Transmission line equations along \( \ell \)

\[
\frac{dV_p^w}{ds} = -jX_p^w I_p^w, \quad X_p^w = \frac{X_p^w}{W}
\]

\[
\frac{dI_p^w}{ds} = -jV_p^w, \quad B_p^w = \frac{(\beta_p^w)^2}{X_p^w} W
\]

\[
Z_{cp}^w = \frac{X_p^w}{B_p^w} W = \frac{\alpha \mu_0}{B_p^w W}
\]

\[
\beta_p^w = \sqrt{\frac{\alpha}{\mu_0} \cdot \left( \frac{p \pi}{W} \right)^2}
\]

### Table 3 Radial normal mode function for H-plane circular bend section

<table>
<thead>
<tr>
<th>( R_n^r(r) ) ( n )-th radial normal mode function</th>
</tr>
</thead>
<tbody>
<tr>
<td>( R_n^r(r) = ) see Table 3 (( n = 1, 2, \ldots ))</td>
</tr>
</tbody>
</table>

#### Analytical solution for \( \beta_p^n(=k_0)=0 \)

\[
R_n^c(r) = -\frac{2}{\ln C} \sin \left( \frac{n C}{\ln C} \right) (n = 1, 2, \ldots)
\]

#### Numerical solution for \( \beta_p^n \neq 0 \) by non-uniform transmission line

\[
\frac{dV_p^c}{dr} = -jX_p^c I_p^c, \quad X_p^c = \frac{X_p^c}{W}
\]

\[
\frac{dI_p^c}{dr} = -jV_p^c, \quad B_p^c = \frac{(\beta_p^c)^2}{X_p^c} W
\]

\[
V_p^c = \frac{X_p^c}{\beta_p^c}, \quad X_p^c = \frac{\alpha \mu_0}{\beta_p^c W}
\]

\[
Z_{cp}^c = \frac{X_p^c}{V_p^c}
\]

#### B.C.

\[
U(T) = 0 \quad (r = a, b)
\]

\[
\frac{dV_p^c}{dr} = 0 \quad (r = a, b)
\]

\[
\frac{dI_p^c}{dr} = 0 \quad (r = a, b)
\]

\[
V_p^c = -j \frac{V_p^c}{\beta_p^c}, \quad X_p^c = \frac{\alpha \mu_0}{\beta_p^c W}
\]

\[
Z_{cp}^c = \frac{X_p^c}{\beta_p^c}
\]

\[
\beta_p^c = \sqrt{\frac{\alpha}{\mu_0} \cdot \left( \frac{p \pi}{W} \right)^2}
\]
3. Calculation of radial normal mode function

The key step in this analysis is the calculation of radial normal mode function \( R_n \) and circular propagation constant \( \beta_n \) defined by (A) in Table 3 as function of operating frequency (or \( \beta_n = k_0 \)) and bend curvature parameter \( \beta_n \). How to calculate them is explained in the following. When mode voltage and mode current along \( r \) are defined in such away as (C) in Table 3, the second order differential equation (A) in Table 3 can be transformed to a nonuniform transmission line equations given by (C) in Table 3.

In order to calculate \( R_n \) and \( \beta_n \) numerically for a given \( \beta_n \) or frequency, this non-uniform transmission line between \( b \) and \( a \) is approximated by cascade connection of infinitesimally small uniform transmission line section as shown in Fig. 3. In our present case, waveguide width \( W = a - b \) is equally divided into \( N \) sections; position dependent original reactance \( x \) and susceptance \( b \) given by (C) in Table 3 are approximated to be the corresponding constant value at the center position of each section, respectively. Then, the corresponding eigenvalue problem is solved by the following way. Assuming \( v_n \), F-matrix of each uniform section \( F_n \) can be easily calculated. Therefore, Total F-matrix between port \( b \) and port \( a \) is given by their cascade product and can be expressed by eq. (3)

\[
\begin{pmatrix}
\beta_n
\end{pmatrix} = \begin{pmatrix} \mathbf{F} \end{pmatrix} \mathbf{F} \cdots \mathbf{F} \begin{pmatrix} \beta_n \end{pmatrix} = \begin{pmatrix} A & B \end{pmatrix} \begin{pmatrix} \beta_n \end{pmatrix}
\]

(3)

Numerical search of \( \beta_n \), which makes \( \beta_n = 0 \), gives \( \beta_n \) and then \( R_n \). Thus calculated circular propagation constants \( \beta_n \) vs normalized frequency for wide range of curvature parameter \( \beta_n \) are shown in Figs.4 and 5, where the normalized frequency is defined as \( F = 2 W / \lambda_0 \) (\( \lambda_0 \) = free space wavelength). Also radial normal mode functions of lower order are shown in Figs. 4 and 5. Through these calculation \( N \) is taken as 200 or above this value. Analytical solution for \( F = 0.0 \) (\( \beta_n = 0 \)) is exactly given by (B) in Table 3, which is practically outside desired frequency band but is used for demonstrating the validity of the present numerical analysis.

4. Frequency characteristics of right angle circular bend

Once the \( R_n \) are obtained, the ideal transformer ratio \( n_{tn} \) defined by eq.(1) is easily calculated; some calculated results are shown in Figs.4 and 5 for \( p = 1 \). By these calculation, the required network parameters of the equivalent multi-transmission line in Fig. 2 are prepared. Therefore, using these network parameters, frequency characteristics of circular bend can be calculated for any bend angle and bend curvature. As an example, frequency characteristic of the VSWR for the right-angle circular bend case are calculated and shown in Fig. 6 with curvature \( \beta_n \) as a parameter.

5. Conclusion

Analytical method which can calculates input/output performance of H-plane circular bend structure is explained based on the equivalent multi-transmission line network representation and applied to the practical structure. Wide band frequency characteristics for right angle circular bend case are calculated as an example for wide range of curvature parameter.
Fig. 5 Circular propagation constant \( v_n(F,C) \), radial mode function of lower mode \( V_n = R_n(r,C,F=1.5) \) and ideal transformer ratio between \( n \)-th radial mode and \( TE_{m0} \) mode \( (n=n_{m1}) \), where curvature parameter \( C \) are taken as 0.1, 0.3, 0.5 and 0.7 and normalized frequency \( F \) is defined by \( 2W/\lambda_0 \). \( (\lambda_0=\text{free space wavelength}) \)
